Fine needle aspiration cytology in the diagnosis of liver lesions. In a retrospective study, the authors reviewed the cytologic and histologic findings of fine needle aspiration (FNA) of 524 hepatic lesions, excluding patients with cystic lesions. In 295 (57%) patients, liver lesions were discovered incidentally during the procedure. The cytologic diagnosis was correct in 89.4% of cases. The specific diagnosis of malignant and benign lesions, respectively, was correctly diagnosed in 96.9% and 71.8% of cases. In 193 (37%) patients, hepatic lesions were followed up by FNA biopsy after some weeks to months, with an overall accuracy of 87.6%. The final diagnosis of hepatic lesions was obtained by liver biopsy in the remaining 25 patients (4.9%). In conclusion, the authors assert that FNAC is the first-line approach to the diagnosis of focal hepatic lesions in most patients. The method described here is for use with existing snowblowers. However, the present invention also can be used with a snowblower being built from scratch, with modification to the blower frame and other parts as described herein. Typically, a snowblower is used to remove snow from a surface, such as the roof of a residence or business. In general, the snow is first spread on a surface, such as the roof, then the snowblower is positioned over the surface and is operated to throw the snow into a windrow. The windrow of snow is then usually picked up by a snowblower operator or some other person, and the snow is transported from the windrow to a storage bin. A problem encountered in the operation of snowblowers is that the volume of snow picked up by the blower can exceed the capacity of the storage bin. In addition, the volume of snow being pushed 2d92ce491b
