The objective of this proposal is to develop a clinically useful method for predicting and preventing central nervous system (CNS) infections with herpes simplex virus (HSV) in patients with malignant diseases of the head. Patients with malignant disease of the head are at an increased risk for developing fatal HSV encephalitis. This appears to be a consequence of either dysfunction in cell-mediated immunity or manipulation of the host immune system by metastatic malignancy or its treatment with immunosuppressive agents. A variety of experimental procedures have been employed to identify patients at highest risk for developing HSV encephalitis, including assessment of humoral immunity and quantitation of T-lymphocyte subsets. While most of these studies have used single assays to measure cellular immunity, few have been based on the combined application of several immunologic techniques. In order to evaluate the potential role of cell-mediated immunity in the pathogenesis of HSV encephalitis, a more comprehensive approach to quantitating the cellular immune response is needed. Using a battery of current tests for measuring cell-mediated immunity, applicants propose to determine whether a reduction in T-lymphocyte function of the host is directly responsible for the development of fatal HSV encephalitis. In order to establish a basis for monitoring the state of cell-mediated immunity in patients with malignant diseases of the head during periods of treatment, the applicants propose to quantitate HSV-specific cellular immunity in patients at different stages of treatment. Overall, this research will help define the underlying defect in
